What is serverless computing?

Introducing Serverless Computing

What is serverless computing?

- **Serverless** is a cloud service that aims to take the pain out of hosting online services and code on the cloud.
- It encapsulates many underlying technologies required to host a web service such as operating system, resource management, and security rules internally, allowing you as the developer to focus on your code.
- Serverless compute is also a **stateless** service, which means the server only runs when a request is received. This helps cut down on resources and allows cost savings since most of the time the server is idle.
